All Banks Great, Small, and Global: Loan pricing and foreign competition

Beatriz de Blas Katheryn Niles Russ

Universidad Autónoma de Madrid

University of California, Davis and NBER

2011 Workshop on Costs and Benefits of International Banking Deutsche Bundesbank What happens to banks' market power when a country begins to allow foreign financial intermediation?

How do these changes in market structure affect aggregate output, consumption, and employment?

・ 同 ト ・ ヨ ト ・ ヨ ト …

Foreign bank lending is important

- Cross-border lending by banks through foreign branches and at arms-length > \$31 trillion (BIS)
- > half the size of world GDP (World Bank)
- > one-third the size of foreign asset holdings totalled across all countries

3 🖌 🖌 3 🕨

Banking is an imperfectly competitive industry

- Almost one quarter of private lending worldwide originates from 15 multinational banks. (Bankscope, Euromoney)
- Empirically, we see net interest margins (NIMs) increase after liberalization toward takeovers by foreign banks, especially in developing countries

|圖 | | 国 | | 国 |

- current models of the open economy (FDI and trade) stress the role of heterogeneity in firm size
- current models of banks stress endogenous markups and head-to-head competition
- No existing model of global banks can address both issues at the same time without limiting the number of banks to \leq 3

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

Existing literature

- Symmetric banks with arms-length foreign lending and endogenous entry
 - Agenor and Aizenman (2008), Ghironi and Stebunovs (2010), Olivero (2010)
- Heterogeneous banks with constant markups
 - Gerali, Neri, Sessa, and Signoretti (2010)
- Heterogeneous banks with FDI, limited number of banks
 - dell'Arriccia and Marquez (2008) and related innovations
- Heterogeneous banks with endogenous markups, all banks charge same interest rate
 - Mandelman 2006 and 2010

What we do

- model a continuum of heterogeneous banks that charge endogenous markups
 - Bertrand price competition
 - ▶ firms who SEARCH for the best interest rate to borrow working capital

듣▶ ★ 듣▶

What we do

- model a continuum of heterogeneous banks that charge endogenous markups
 - Bertrand price competition
 - ▶ firms who SEARCH for the best interest rate to borrow working capital
- allow for arms-length cross-border lending
 - reduces markups over the cost of lending that banks charge borrowers

What we do

- model a continuum of heterogeneous banks that charge endogenous markups
 - Bertrand price competition
 - ▶ firms who SEARCH for the best interest rate to borrow working capital
- allow for arms-length cross-border lending
 - reduces markups over the cost of lending that banks charge borrowers
- allow for takeovers of domestic banks by foreign ones
 - transfer of superior technology allows target bank to increase its markup without raising interest rates charged to borrowers

Consumers

- choose to consume or save real income
- save wealth in the form of bank deposits
- receive (endogenous) interest rate \bar{r} on deposits

э

⊸ ≣ ⊁

- a continuum on the [0,1] interval
- produce with identical technology

$$y(i) = h(i)^{1-\alpha}$$

- borrow to finance the wage bill (working capital)
- apply to a fraction *n* of all existing banks *J* when searching for a lender due to the burden of application fees
- get *nJ* interest rate quotes and use them to bargain with each potential lender

Transfer savings to firms in the form of working capital

æ

・ロン ・雪 と ・ ヨ と ・ ヨ と …

Transfer savings to firms in the form of working capital

• have heterogeneous screening/monitoring abilities that yield marginal cost of lending $C_k(i)$, where k = 1 represents the lowest-cost bank to which some firm i applies for a loan

・ロト ・聞 ト ・ ヨト ・ ヨト

Transfer savings to firms in the form of working capital

- have heterogeneous screening/monitoring abilities that yield marginal cost of lending $C_k(i)$, where k = 1 represents the lowest-cost bank to which some firm i applies for a loan
- charge a markup over the cost of lending, differs for each firm *i*

Transfer savings to firms in the form of working capital

- have heterogeneous screening/monitoring abilities that yield marginal cost of lending $C_k(i)$, where k = 1 represents the lowest-cost bank to which some firm i applies for a loan
- charge a markup over the cost of lending, differs for each firm *i*
- markup never exceeds the point where MC=MR, $\bar{m}(i)$

Transfer savings to firms in the form of working capital

- have heterogeneous screening/monitoring abilities that yield marginal cost of lending $C_k(i)$, where k = 1 represents the lowest-cost bank to which some firm i applies for a loan
- charge a markup over the cost of lending, differs for each firm *i*
- markup never exceeds the point where MC=MR, $\bar{m}(i)$
- markup never exceeds the marginal cost of the second-best bank to which firm *i* applies

$$M(i) = \min\left\{\frac{C_2(i)}{C_1(i)}, \bar{m}(i)\right\}$$

If we suppose that bank cost parameters are drawn from a Weibull distribution...

then increasing the number of banks to which firms apply results (on average) in a lower markup and interest rate charged to any firm i.

• bank-level data for 80 countries from Bankscope in the year 2000

э

Liberalizing to allow arms-length cross-border lending has an effect similar to expanding search

- markups fall
- interest rates on loans fall

э

(日) (同) (三) (三)

Liberalizing to allow arms-length cross-border lending has an effect similar to expanding search

- markups fall
- interest rates on loans fall

Liberalizing to cross-border takeovers is quite different

- transfer of superior technology from parent makes a target bank even more efficient than its next best rival for any customer *i*
- markups increase
- target banks can not increase interest rates after a takeover (risk driving their customers to send out more loan applications)

Confronting the data

Our market structure effect from takeovers appears quantitatively important compared to information externalities.

- externality: merged banks can exploit new cost advantage over competitors by raising rates on continuing borrowers
 - only a few micro studies have matched data to explore this
 - Sapienza (2002), Montoriol-Garriga (2008), Hetland and Mjos (2010), Gormley (2010), Erel (2011)
 - no evidence that continuing borrowers face higher rates, despite obvious cherrypicking

Confronting the data

Our market structure effect from takeovers appears quantitatively important compared to information externalities.

- externality: merged banks can exploit new cost advantage over competitors by raising rates on continuing borrowers
 - only a few micro studies have matched data to explore this
 - Sapienza (2002), Montoriol-Garriga (2008), Hetland and Mjos (2010), Gormley (2010), Erel (2011)
 - no evidence that continuing borrowers face higher rates, despite obvious cherrypicking
- borrowers dropped after merger should face higher rates from inferior lenders
 - only one micro study has matched data to explore this
 - Montoriol-Garriga (2008)
 - no statistically significant change in rates for borrowers who change lenders post-merger, even controlling for risk profile

イロト 不得 とうせい かほとう ほ

Arms-length cross-border lending increases aggregate output, consumption, and employment more than cross-border takeovers

• especially when domestic contestability is low or domestic financial technologies are inferior (or both!!)

Cross-border takeovers have little effect on aggregate outcomes at all

Both policies are welfare-neutral

• decreasing returns to scale means that increases in working hours offset the effects of any increases in consumption on welfare

A I > A I > A

A new framework to analyze lending behavior when banks are large, small, and sometimes global.
